# "Hyper"parameters vs model parameters

- Let's look at an example dataset:

```
head(breast_cancer_data)
```

```
# A tibble: 6 x 11
  diagnosis concavity_mean symmetry_mean fractal_dimension
  <chr>              <dbl>          <dbl>              <dbl>
1 M                 0.300          0.242             0.0787
2 M                 0.0869         0.181             0.0567
3 M                 0.197          0.207             0.0600
4 M                 0.241          0.260             0.0974
```

- And build a simple **linear model**.

# Let's start simple: Model parameters in a linear model

```
# Create linear model
linear_model <- lm(perimeter_worst ~ fractal_dimension_mean
```

```
# Get coefficients
linear_model$coefficients
```

```
                      Estimate Std. Error t value Pr(>|t|)
(Intercept)             167.60      25.91   6.469  3.9e-09
fractal_dimension_mean -926.39     392.86  -2.358   0.0204
```

# Let's start simple: Model parameters in a linear model

- Model **parameters** are being fit (i.e. found) during training.
- They are the **result** of model fitting or training.
- In a linear model, we want to find the **coefficients**.

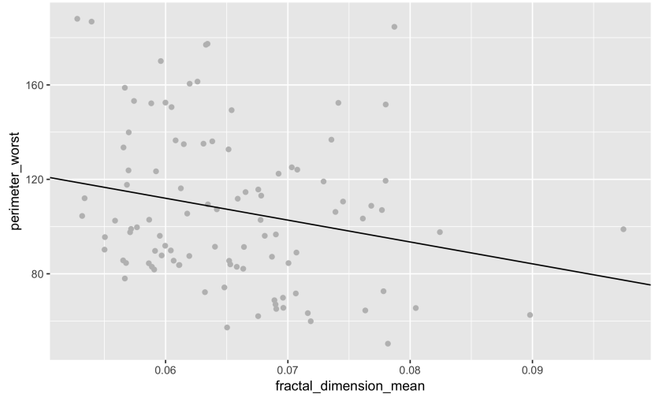
```
linear_model$coefficients
```

```
(Intercept) fractal_dimension_mean
   167.5972                -926.3866
```

- We can think of them as the **slope** and the **y-intercept** of our model.

# Coefficients in a linear model

```
ggp <- ggplot(data = breast_cancer_data,
              aes(x = fractal_dimension_mean, y = perimeter_worst)) +
       geom_point(color = "grey")
ggp + geom_abline(slope = linear_model$coefficients[2],
                  intercept = linear_model$coefficients[1])
```



# Model parameters vs hyperparameters in a linear model

- *Remember*: model **parameters** are being fit (i.e. found) during training; they are the **result** of model fitting or training.
- **Hyperparameters** are being set before training.
- They specify **HOW** the training is supposed to happen.

```
args(lm)
help(lm)
?lm

linear_model <- lm(perimeter_worst ~ fractal_dimension_mean,
                   data = breast_cancer_data,
                   method = "qr")
```

# Parameters vs hyperparameters in machine learning

In our **linear model**:

- Coefficients were **found** during fitting.
- `method` was an option to set **before** fitting.

In **machine learning** we might have:

- Weights and biases of neural nets that are optimized during training => model **parameters**.
- Options like learning rate, weight decay and number of trees in a Random Forest model that can be tweaked => **hyperparameters**.

# Why tune hyperparameters?

- Fantasy football players ~ **Hyperparameters**
- Football players' positions ~ Hyperparameter **values**
- Finding the best combination of players and positions ~ Finding the best **combination** of hyperparameters

# Let's practice!

HYPERPARAMETER TUNING IN R

# Recap of machine learning basics

HYPERPARAMETER TUNING IN R

datacamp

# Machine learning with caret - splitting data

```
# Load caret and set seed
library(caret)
set.seed(42)

# Create partition index
index <- createDataPartition(breast_cancer_data$diagnosis, p = .70,
                             list = FALSE)
# Subset `breast_cancer_data` with index
bc_train_data <- breast_cancer_data[index, ]
bc_test_data  <- breast_cancer_data[-index, ]
```

- Training set with enough **power**.
- **Representative** test set.

# Train a machine learning model with caret

- Set up **cross-validation**:

```
library(caret)
library(tictoc)
fitControl <- trainControl(method = "repeatedcv", number = 3, repeats = 5)
```

- **Train** a Random Forest model:

```
tic()
set.seed(42)
rf_model <- train(diagnosis ~ ., data = bc_train_data, method = "rf", trContro
                  verbose = FALSE)
toc()
```

```
1.431 sec elapsed
```

# Automatic hyperparameter tuning in caret

```
Random Forest

...

Resampling results across tuning parameters:

  mtry  Accuracy   Kappa
   2    0.9006783  0.8015924
   6    0.9126645  0.8253289
  10    0.8999389  0.7999386

Accuracy was used to select the optimal model using the lar
The final value used for the model was mtry = 6.
```

## 6 Available Models

The models below are available in `train`. The code behind these protocols can be obtained using the function `getModelInfo` or by going to the github repository.
